Experiment No. 4

Title: Creating functions, classes and objects using python

Aim: To study and create functions, classes and objects using python

Objective: To introduce functions, classes and objects in python

Theory:

A function is a block of code which only runs when it is called.

You can pass data, known as parameters, into a function.

A function can return data as a result.

A class is a user-defined blueprint or prototype from which objects are created. Classes provide a means of bundling data and functionality together. Creating a new class creates a new type of object, allowing new instances of that type to be made. Each class instance can have attributes attached to it for maintaining its state. Class instances can also have methods (defined by their class) for modifying their state.

To understand the need for creating a class let's consider an example, let's say you wanted to track the number of dogs that may have different attributes like breed, age. If a list is used, the first element could be the dog's breed while the second element could represent its age. Let's suppose there are 100 different dogs, then how would you know which element is supposed to be which? What if you wanted to add other properties to these dogs? This lacks organization and it's the exact need for classes.

Class creates a user-defined data structure, which holds its own data members and member functions, which can be accessed and used by creating an instance of that class. A class is like a blueprint for an object.

Code:

```python
class Student:

    def __init__(self, name, age, grade):

        self.name = name

        self.age = age

        self.grade = grade

    def study(self):

        print(f"{self.name} is studying hard.")

    def get_grade(self):

        return self.grade

# Creating objects of the Student class

student1 = Student("Ally", 17, "A")

student2 = Student("Manny", 16, "B")

# Accessing object attributes

print(f"{student1.name} is {student1.age} years old and got a grade of {student1.get_grade()}.")

print(f"{student2.name} is {student2.age} years old and got a grade of {student2.get_grade()}.")

# Calling object methods

student1.study()

student2.study()
```

Output:

```
PORTS    SEARCH ERROR    COMMENTS    PROBLEMS    DEBUG CONSOLE    OUTPUT

PS C:\Users\gawad\OneDrive\Desktop\python> python -u "c:\Users\ga
Ally is 17 years old and got a grade of A.
Manny is 16 years old and got a grade of B.
Ally is studying hard.
Manny is studying hard.
PS C:\Users\gawad\OneDrive\Desktop\python>
```

Conclusion:

The code is about students represented by a `Student` class in Python. It holds details like name, age, and grade, and offers methods for studying and getting grades. By creating student objects, we can keep track of individual students and perform actions like studying. This illustrates how Python's object-oriented programming works, providing a neat way to organize and work with data about students in our program.
